A look into the Mobile Messaging Black Box

33rd Chaos Commmunication Congress #33c3

Roland Schilling   @NerdingByDoing

Hamburg University of Technology
Security in Distributed Applications

Introduction

- You're at a party
- Friend approaches you and needs to tell you something in private
- What do you expect when you say private?
- You enter a separate room, you trust the location
- What does a separate room offer you?
    - Confidentiality
    - Authenticity
    - Integrity
    - Forward Secrecy
    - Future Secrecy
    - Plausible Deniability

You are now alone in a closed room with your Friend

- Both of you have absolute Confidentiality that you are alone
- Nobody can overhear your talk
- Your exchange is completely private

We call this confidentiality
The room you're in is small enough that you can always see each other

- You know that the words you speak are received just as you spoke them
- There is no way either of you hears something other than the other says

We call this integrity

Since you're long-time friends, you're absolutely sure, whom you're talking to

- Nobody can impersonate your friend or you, without the other noticing
- You're talking directly, without a phone or webcam in between

We call this authenticity

Suppose somebody was present in the room with you

- They could overhear your conversation
- They would only learn the contents of this particular conversation
- They would not learn anything about past conversations you had

We call this forward secrecy

$\rightarrow$ They would also not learn anything about future conversations you might have

We call this future secrecy

Perfect Forward- and Future Secrecy

secure messages

compromised messages

timeline

Perfect Forward Secrecy

Future Secrecy

key compromised

There are no witnesses in the room

- Either of you can later deny to other having made any statement
- Neither of you can prove to other that any of you have made a particular statement

We call this deniability

Enter Messaging Services

Parties involved

- Depending on the scenario, at least one additional party is involved, the messaging provider
- push message provider might also be involved
- In federated scenarios, multiple relaying parties may be involved
- $\Rightarrow$ Messaging solutions should be designed so as to minimized the data these parties may obtain

Problems:

- How to find your peers? (address book leakage)
- How to relay messages to the recipient? (participation leakage)
- Relay always knows the exact time a message was sent
- Relay always knows the size of transmitted messages (padding helps)

What if this conversation had taken place via SMS?

Your providers

- would know the contents of your exchange: no confidentiality
- could change the contents of your exchange: no integrity
- could reroute your messages and impersonate either of you: no authentication
- would know all messages you ever exchanged: no forward Secrecy
- would know all messages exchanged in the future: no future secrecy
- could store all messages and use them as proof of the exchange: no deniability

Messaging translates badly to our offline communication expectation
From:
either of us
or nobody

33c3
WORKS FOR EM

To:
both of us
or nobody

Symmetric Encryption:
→ Encryption and decryption with the same key

Symmetric Encryption:
$\rightarrow$ Encryption and decryption with the same key
Symmetric Encryption:
  → Encryption and decryption with the same key

Key		Key

plain text → **Crypto** → ciphertext → **Crypto** → plain text

Asymmetric Encryption:
  → Encryption and decryption with different keys

Key		Key
plain text → **Crypto** → ciphertext → **Crypto** → plain text

Symmetric Encryption:

→ Encryption and decryption with the same key

```
                    Key                              Key
                     ↓                                ↓
 plain text  →    Crypto    →   ciphertext   →     Crypto     →   plain text
```

Asymmetric Encryption:

→ Encryption and decryption with different keys

```
                    Key      ←   key pair   →       Key
                     ↓                                ↓
 plain text  →    Crypto    →   ciphertext   →     Crypto     →   plain text
```
Secret Key **Public Key** **Identity**

Secret Key **Public Key** **Identity**

- Both parties publish their identities and public keys
- Any message can be encrypted with anyone's public key and only be decrypted with its corresponding secret key

- Both parties publish their identities and public keys
- Any message can be encrypted with anyone's public key and only be decrypted with its corresponding secret key

Cryptography is rarely, if ever, the solution to a security problem. Cryptography is a translation mechanism, usually converting a communications security problem into a key management problem.

—Dieter Gollmann

- identity keys stored on devices, what if stolen
- keys for back-end communication layer hard-coded, almost impossible to replace
- how to deal with key compromise? (answer: key rotation)
- How to connect a key to a person?
    - $\rightarrow$ Key signing (PGP)
    - $\rightarrow$ Certificates (trusted third party)
    - $\rightarrow$ Service directory (based on phone numbers or email addresses)
- How to deal with changing keys?
    - warnings are annoying
    - Threema's traffic light system encourages authentication but doesn't

Case Study - Signal

Signal - Notes

- Server-side cached short-term keys (prekeys) fetched by sender
- Pairwise long-lived symmetric secret key between participants
- Multiple messages without answer → perform KDF on chaining key
- ECDH: Curve25519, AES-CTR (no padding), AES-CBC (PKCS7 padding)
- HMAC-SHA256 for integrity
- Future secrecy only if private keys are not leaked (duh!). Since private keys go into new shared keys during ratcheting, the attacker lacks material to compromise next key after obtaining current one.
- Since shared keys are only deleted after messages are received, there is a window in which keys could be compromised before reception.
- Deniability is always a theoretical claim as long as a transmission server has the ability to log messages, their senders and recipients.

Reverse-Engineering Threema

Threema

- Gained popularity in Germany after Facebook purchased WhatsApp
- All promise – no proof; first openly contemplating to OSS the code, later backing away from that statement
- Interest in its inner workings

Quick Shoutouts

- Jan Ahrens for releasing his findings about the handshake before we did
- OpenMittsu for releasing the first working OSS client

- Test for common pitfalls in implementation
  - Handling of TLS
  - Handling of keys and nonces
  - NaCl implementation errors
  - Uncommon data leaks
  - Bugs
  - …?
- Find out how protocol is designed
  1. Understand handshakes
  2. Understand protocol
  3. decipher messages

Positive side-note: Threema had released a security white paper early on

Notes:

- PFS only on transport layer (attacker sniffing packets from the outside will not learn contents after private key acquisition)

Q:

- How often is the handshake performed?

Image outlining the whole architecture, e2e, REST, file upload, user authentication, account management, etc..
Threema Packet Format

- Polls
- Images with Caption
  - Case of caption leak found
- Audio Messages
 - Leak Android version
  - Possible StageFright vector

- Audio length is lost on forwarding

- Group IDs aren't unique. They are created locally and only work together with the group creator's ID
- The structure of group messages makes it impossible for Threema to introduce multiple group administrators on a protocol level without breaking compatibility to older clients

Done!

Thank You!

Thanks to Jan Ahrens and Philipp Berger – their work has made ours somewhat easier
Thanks to Maximilian Köstler for his initial work on Threema
